# Does the peripheral drift illusion work on other organisms?

# Yes!

# Multiple views

stereo vision structure from motion optical flow

# Why multiple views?

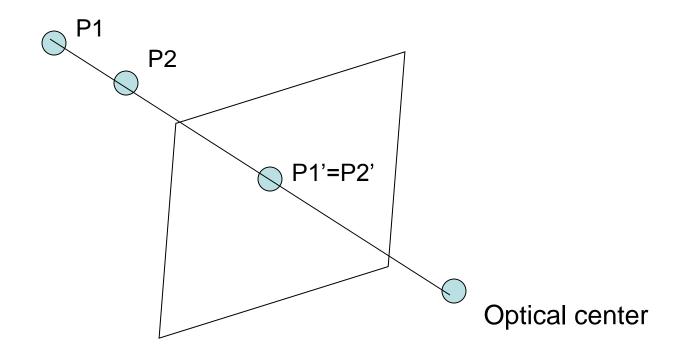

Structure and depth are inherently ambiguous from single views.

# Geometry for a simple stereo system

 First, assuming parallel optical axes, known camera parameters (i.e., calibrated cameras):

# Geometry for a simple stereo system

 Assume parallel optical axes, known camera parameters (i.e., calibrated cameras). What is expression for Z?

Similar triangles  $(p_l, P, p_r)$  and  $(O_l, P, O_r)$ :

$$\frac{T + x_l - x_r}{Z - f} = \frac{T}{Z}$$

$$Z = f \frac{T}{x_r - x_l}$$
 disparity

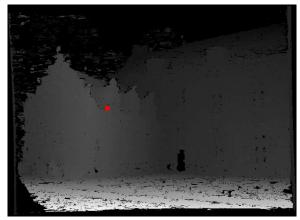

# Depth from disparity

image I(x,y)

Disparity map D(x,y)

image I'(x',y')

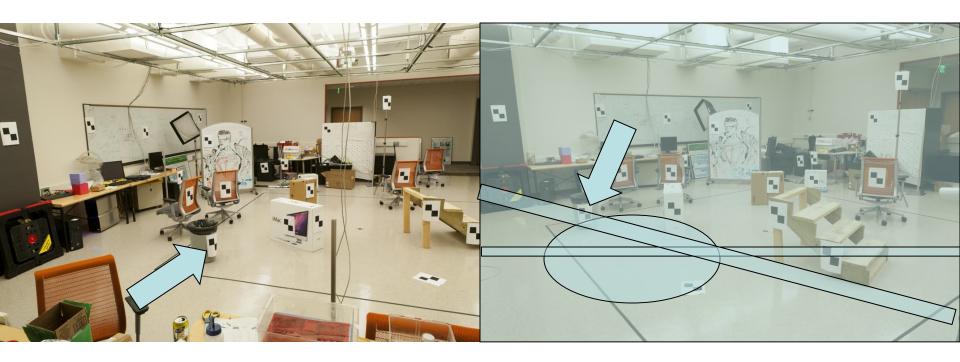

$$(x',y')=(x+D(x,y), y)$$

So if we could find the **corresponding points** in two images, we could **estimate relative depth**...

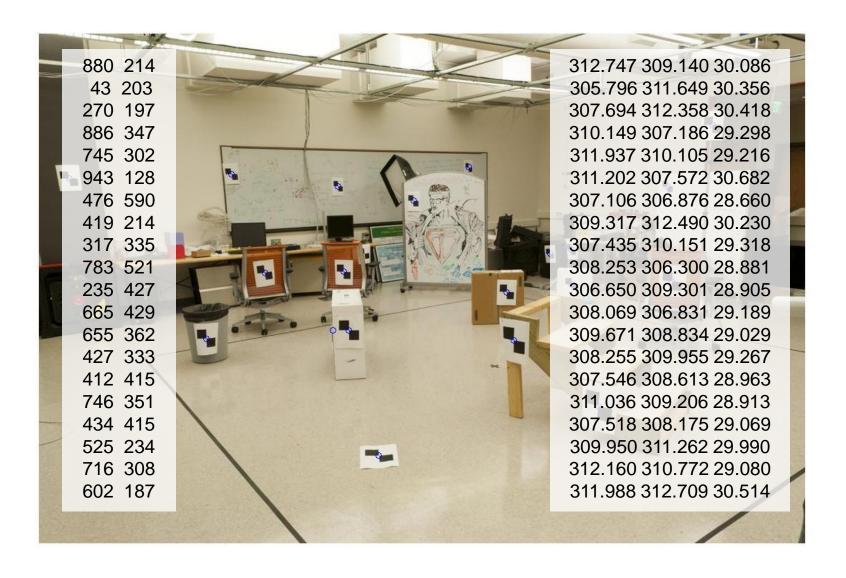

# What did we need to know?

- Correspondence for every pixel. Sort of like project 2, but project 2 is "sparse" and we need "dense" correspondence.
- Calibration for the cameras.

# Beyond Pinholes: Radial Distortion

- Common in wide-angle lenses or for special applications (e.g., security)
- Creates non-linear terms in projection
- Usually handled by through solving for non-linear terms and then correcting image

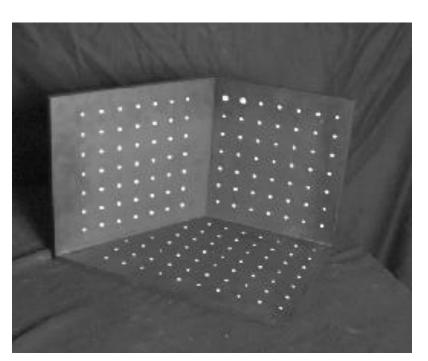

**Corrected Barrel Distortion** 

How to calibrate the camera? (also called "camera resectioning")

# Calibrating the Camera

Use an scene with known geometry

- Correspond image points to 3d points
- Get least squares solution (or non-linear solution)

### Calibration with linear method

- Advantages
  - Easy to formulate and solve
  - Provides initialization for non-linear methods
- Disadvantages
  - Doesn't directly give you camera parameters
  - Doesn't model radial distortion
  - Can't impose constraints, such as known focal length
- Non-linear methods are preferred
  - Define error as difference between projected points and measured points
  - Minimize error using Newton's method or other non-linear optimization

# Can we factorize M back to K [R | T]?

- Yes!
- You can use RQ factorization (note not the more familiar QR factorization). R (right diagonal) is K, and Q (orthogonal basis) is R. T, the last column of [R | T], is inv(K) \* last column of M.
  - But you need to do a bit of post-processing to make sure that the matrices are valid. See http://ksimek.github.io/2012/08/14/decompose/

# Can we factorize M back to K [R | T]?

- Yes!
- Alternatively, you can more directly solve for the individual entries of K [R | T].

For project 3, we want the camera center

# Recovering the camera center

This is not the camera center C. It is -RC (because a point will be rotated before  $t_x$ ,  $t_y$ , and  $t_z$  are added)

So we need -R<sup>-1</sup> K<sup>-1</sup> m<sub>4</sub> to get C

This is  $\mathbf{t} * \mathbf{K}$ So  $\mathbf{K}^{-1} \mathbf{m}_4$  is  $\mathbf{t}$ 

Q is K \* R. So we just need  $-Q^{-1}$  m<sub>4</sub>
